#### **ABSTRACT**

Spatial distribution the ambient temperature, relative humidity and air velocity were determined for different storage temperatures such as 0 °C, 1 °C, 2 °C and 3 °C in an experimental cold store. Mapping software were used to show the variability.

Spatial distribution of the temperature and the relative humidity was not uniform in the cold store. Reason of bad spatial distributions was bad spatial distribution of air velocity distributed by evaporator. A temperature and/or a relative humidity sensor are used in cooling systems to measure temperature and relative humidity. The umber of sensors are not enough to determine variability of temperature and relative humidity. There should be additional sensors located different places to give idea for cold storage.

Key words: Cold store, ambient temperature, relative humidity, air velocity, spatial distribution

# INTRODUCTION

Deterioration of fruits and vegetables during the storage depends largely on temperature. One way to slow down this change and so increase the length of time fruits and vegetables can be stored, is by lowering the temperature to an appropriate level.

For most produce, a high but not saturated, relative humidity is required, eg. 85-95%.

shows specific relative humidity for fruits and vegetables. There is always some moisture loss during cold storage but excessive moisture loss is a problem. It is essential that the relative humidity is kept above 85%.

Temperature variation is minimized with adequate air circulation. Most stores are designed to provide an airflow of 0.3m³/min. per ton of product, based on the maximum amount of product that can be stored in the room. This is needed to cool product to storage temperature and also may be needed if the product has a high respiration rate. This high airflow rate can cause excessive weight loss from products, and fans are a significant source of heat, so the system should be designed to reduce airflow to 0.06 m³/min to 0.12 m³/min. of airflow per ton Motor speed control systems, such as variable rate –frequency control controllers for alternating current motors, are used to control fan speed at the lowest possible speed that will prevent unacceptably warm product in the storage [2].

Most storage facilities use mechanical refrigeration to control storage temperature. The cooling system consists of a condenser, compressor, evaporator, refrigerant, expansion valve, lines and other related parts.

Storage temperature and relative humidity are usually measured from the back of the evaporator in a cold store. Cooling system sets due to this measured temperature value. However, distribution of the temperature and relative humidity in a cold store is generally not same because the ventilation of the air affects the distribution of the cold store temperatures.

Bad temperature control and low relative humidity are some of the problems in the cold storage [5].

The spatio-temporal temperature distribution in the imperfectly mixed airspace around plants has a considerable effect on the physiological plant processes. In a fully instrumented climate chamber, eight identification experiments were carried out to model the spatio-dynamic temperature response around plants to variations in the supply air temperature and the sensible heat, produced by the lamps (directly related to the light intensity), as control inputs. From the experimental data, a minimally parameterized, linear, discrete—time transfer function matrix (TFM) model was identified, capturing the dominant model behavior of the dynamic

process. Based on statistical considerations, a first–order TFM model came out as the best model structure. The first–order model provided a good compromise between goodness of fit and parametric efficiency (standard error), characterized the airflow behavior very well, and formed an adequate basis for model–based process control [3]. Air velocity should be 0.2 m/s. Its mean is equivalent

Air velocity should be 0.2 m/s. Its mean is equivalent velocity to change empty volume of cold store for 25-30 times per hour [4].

Airflow inside a cold store is investigated using computational fluid dynamics. The airflow model is based on the steady state incompressible, Reynolds-averaged Navier±Stokes equations. The turbulence is taken into account using a k; "model. The standard as well as the Renormalisation-Group (RNG) version of the k; "model is investigated. The forced circulation air cooler unit is modeled with an appropriate body force and resistance, corresponding to the characteristics of the fan and the tube-bank evaporator [6].

Spatial distribution of the air velocity, ambient temperature and relative humidity is important to protect agricultural product in a cold store. Aim of this article is to show spatial variability of the temperatures, relative humidity and air velocity in a cold store. In this research; an experimental cold store was used for this aim. Temperatures, relative humidity and air velocity of different places in the experimental cold store were measured to determine spatial distribution of these factors. Ambient temperatures, relative humidity and air velocity were determined at ceiling, medium and floor level in the cold store for different storage temperatures as 0 °C, 1 °C, 2 °C and 3 °C. The results were used to produce spatial distribution maps of ambient temperature, relative humidity and air velocity.

# **MATERIALS**

#### **Cold store**

Dimensions of cold storage were (length x width x height) 4.52 m in length x 1.90 m in width x 2.22 m in height. The volume of the cold store was 19.07 m³. A compressor was located in the outside of the cold store. A condenser, a condenser ventilator, a fluid hopper and a drier were gathered as a group inside the compressor chassis. An evaporator was put on the ceiling of the cold storage with steel screws. Thermostatic expansion valve was fitted in the evaporator inlet and on the high-pressure side of the compressor. A control panel, which includes a thermometer-thermostat, a manometer and a humidity gauge, was placed on the front wall of the cold store. The refrigerant was R404A.

The compressor was a hermetic type and its capacity was

10460 kJ/h. An electrical motor of 1.49 kW powered the compressor. The condenser was cooled by air. It consists of copper pipes, aluminum plates and an axial type ventilator. Its capacity was 12540 kJ/h. The evaporator was made of copper pipes and outside surface covered with aluminum plates. An axial ventilator was located on the back of the evaporator to distribute the cooled air into the cold store. An electrical heater was used to defrost. The capacity of evaporator was 10460 kJ/h.

#### **SENSORS**

Measurement limits of the temperature sensors ranged between -20°C and +100°C. Accuracy of the temperature sensors was  $\pm$  1%. Measurement limits of the relative humidity sensors ranged between 0 % and 100%. Accuracy of the relative humidity sensors was  $\pm$  5 %. Measurement limits of the air velocity sensors ranged between 0 m/s and 20 m/s. Accuracy of the relative humidity sensors was  $\pm$  1%.

# **METHODS**

Ambient temperature, relative humidity and air velocity of different places in this the cold store were measured to determine spatial distribution of these factors. Ambient temperatures, relative humidity and air velocity were measured in top, medium and floor of the cold store for different storage temperatures as 1 °C, 2 °C, 3 °C and 4°C. The results were used to produce spatial distribution maps for temperatures, relative humidity and air velocity.

Measurement points are given in Figure 1.

Surfer Graphic Programme was used to create maps.

Measured data arranged in a file to use by Surfer Programme. Surfer Programme created grid data files. The grid data files were used to create contour maps [1]. The maps were investigated to determine changing of the temperature, air velocity and relative humidity in the cold store.

The results of the air velocity, ambient temperatures and relative humidity were evaluated by using mean, maximum, minimum, standard deviation, and coefficient of variation (CV) [7].

# **RESULTS**

Spatial distribution of the air velocity, ambient temperature and relative humidity are given in figure 2, figure 3, figure 4 and figure 5. Descriptive statistics of the data used to create maps are given table 1, table 2, table 3 and table 4.

Figure 1 is showing that there is variability between air velocity values of top, middle and bottom level of the cold store. When Figure 1 and Table 1 investigated, air velocity and maximum CV (%) can be determined as 2.93m/s, 136.76 % for top level located in front of evaporator. Variation of the air velocity at the middle and bottom of the cold store were less then that top level of the cold store because evaporator was placed at top of the cold store.

Variation of the ambient temperature of the cold store at 0 °C storage temperature changed between 0.1 °C and 2.9 °C. Coefficient of variations of top, middle and bottom level at the cold store were 40.5 %, 24.98 % and 28.51 %, respectively. Maximum CV was determined for top

level because maximum air velocity variation was also determined for the top level of the cold store.

Ambient relative humidity of the cold store was not controlled by the cooling system, automatically. But the coefficient of variation of the relative humidity was changed between 4.33 % and 5.31 %. It is good. The variation of the relative humidity was small because researchers controlled relative humidity during the experiments.

Variation of the ambient temperature of the cold store at 1°C storage temperature changed between 1.5 °C and 3.9 °C. Coefficient of variations of top, middle and bottom level at the cold store were 27.17 %, 21.55 % and 21.92 %, respectively.

The coefficient of variation of the relative humidity was changed between 3.59 % and 5.13 %. The relative humidity was changed between 81.1 % and 95 %.

The ambient temperature at 2°C storage temperature changed between 2.7°C and 5.3°C. Coefficient of variations of top, middle and bottom level at the cold store were 19.76 %, 15.19 % and 15.17%, respectively.

The coefficient of variation of the relative humidity was changed between 3.59 % and 5.13 %. The relative humidity was changed between 85.2% and 95%.

Variation of the ambient temperature of the cold store at 3°C storage temperature changed between 3.5°C and 5.7°C. Coefficient of variations of top, middle and bottom level at the cold store were 10.66 %, 9.45 % and 12.26%, respectively.

The coefficient of variation of the relative humidity was changed between 0.49~% and 1.81~%. The relative humidity was changed between 90.30~% and 95~%.

# **CONCLUSIONS**

Spatial distribution of the air velocity, ambient temperature and relative humidity is important to protect agricultural product in a cold store. In this research an experimental cold store was used to determine spatial distribution of the air velocity, ambient temperature and relative humidity. Temperature and relative humidity sensors are generally located at one point of a cold room. Temperature and relative humidity can measure only one point and the cooling system can be set due to this measured values. The measurements of these sensors are not enough to get a decision for storage temperature and relative humidity. There should be additional sensors located different places to give idea for cold storage. The storage temperature is controlled by the coling system. The relative humidity of the cold store is not generally controlled automatically in practice. Wet jute sack used to control humidity in cold stores.

The ambient temperatures, the relative humidity and the air velocity were determined at ceiling, medium and floor level in the cold store for different storage temperatures as 0°C, 1°C, 2°C and 3°C. Mapping software and descriptive statistics (mean, maximum, minimum, standard deviation and coefficient of variation) were used to evaluate spatial distribution of these data in a cold store.

The air velocity changed between 0 m/s and 2.9, m/s. Coefficient of the variation for ceiling and floor (136,76 % and 124.17 %, respectively) of the cold store was bigger than that middle of the cold store 820.06%).

Ambient temperature varied between 0.1°C and 2.9°C for 0°C storage temperature, 1.5°C and 3,9°C for 1°C storage temperature, 2.7°C and 5.3°C for 2°C storage temperature, 3.5°C and 5.7°C for 3°C storage temperature.

Ambient relative humidity changed between 80.60% and 95% for  $0^{\circ}$ C storage temperature, 81.1% and 95% for  $1^{\circ}$ C storage temperature, 85.20% and 95% for  $2^{\circ}$ C storage temperature, and 90.30% and 95% for  $3^{\circ}$ C storage temperature.

The results showed that distribution of the ambient temperature and the relative humidity was not uniform for this experimental system. Reason of bad spatial distribution of ambient temperature is bad spatial distribution of air velocity generated by evaporator fan. Mapping software can be used to show spatial distribution of the storage factors such as temperature, relative humidity and air velocity for a cold storage to apply best management techniques. Bad distribution area for ambient temperature, relative humidity, and air velocity can be determined by using these maps. If it is required, ventilation of the air can be directed to the bad distribution area or added new ventilation units to correct bad distributions of these factors in a cold store.

Further investigation should be done for different cooling systems and then solutions of the determined problems should be investigated.
